The lab required me to build a one-page ICT461 registration form with semantic HTML (header, fieldset/legend), responsive CSS, one JS interaction (live custom validation messages). The client-side techniques used are ; required, minlength, pattern with regex, and JS listening for the invalid event to swap in readable messages instead of the browser's generic ones and novalidate on the form so the JS is fully in control of when/how errors show.

For the JavaScript interaction, I used an event listener to detect when the registration form is submitted. I used `event.preventDefault()` to prevent the browser from refreshing the page and `checkValidity()` to determine whether the required fields had been completed correctly. If the form is incomplete, a validation message is displayed. When the form is valid, a successful registration message is displayed.

The following must also be validated on the server:

- **Presence and type checks** on all four fields
- **Format/pattern re-validation** — student ID and course code regex checks again, server-side.
- **Authentication/authorization**
- **Rate limiting / CSRF protection** on the POST endpoint itself.

Overall, this lab helped me connect HTML, CSS, and JavaScript into a functional web interface. It also improved my understanding of form validation, responsive design, accessibility, JavaScript events, and basic debugging using browser developer tools.
